Author information

Abstract

When pluripotency factors are removed, embryonic stem cells (ESCs) undergo spontaneous differentiation, which, among other lineages, also gives rise to cardiac sublineages, including chamber cardiomyocytes and pacemaker cells. Such heterogeneity complicates the use of ESC-derived heart cells in therapeutic and diagnostic applications. We sought to direct ESCs to differentiate specifically into cardiac pacemaker cells by overexpressing a transcription factor critical for embryonic patterning of the native cardiac pacemaker (the sinoatrial node). Overexpression of SHOX2 during ESC differentiation upregulated the pacemaker gene program, resulting in enhanced automaticity in vitro and induced biological pacing upon transplantation in vivo. The accentuated automaticity is accompanied by temporally evolving changes in the effectors and regulators of Wnt signaling. Our findings provide a strategy for enriching the cardiac pacemaker cell population from ESCs.

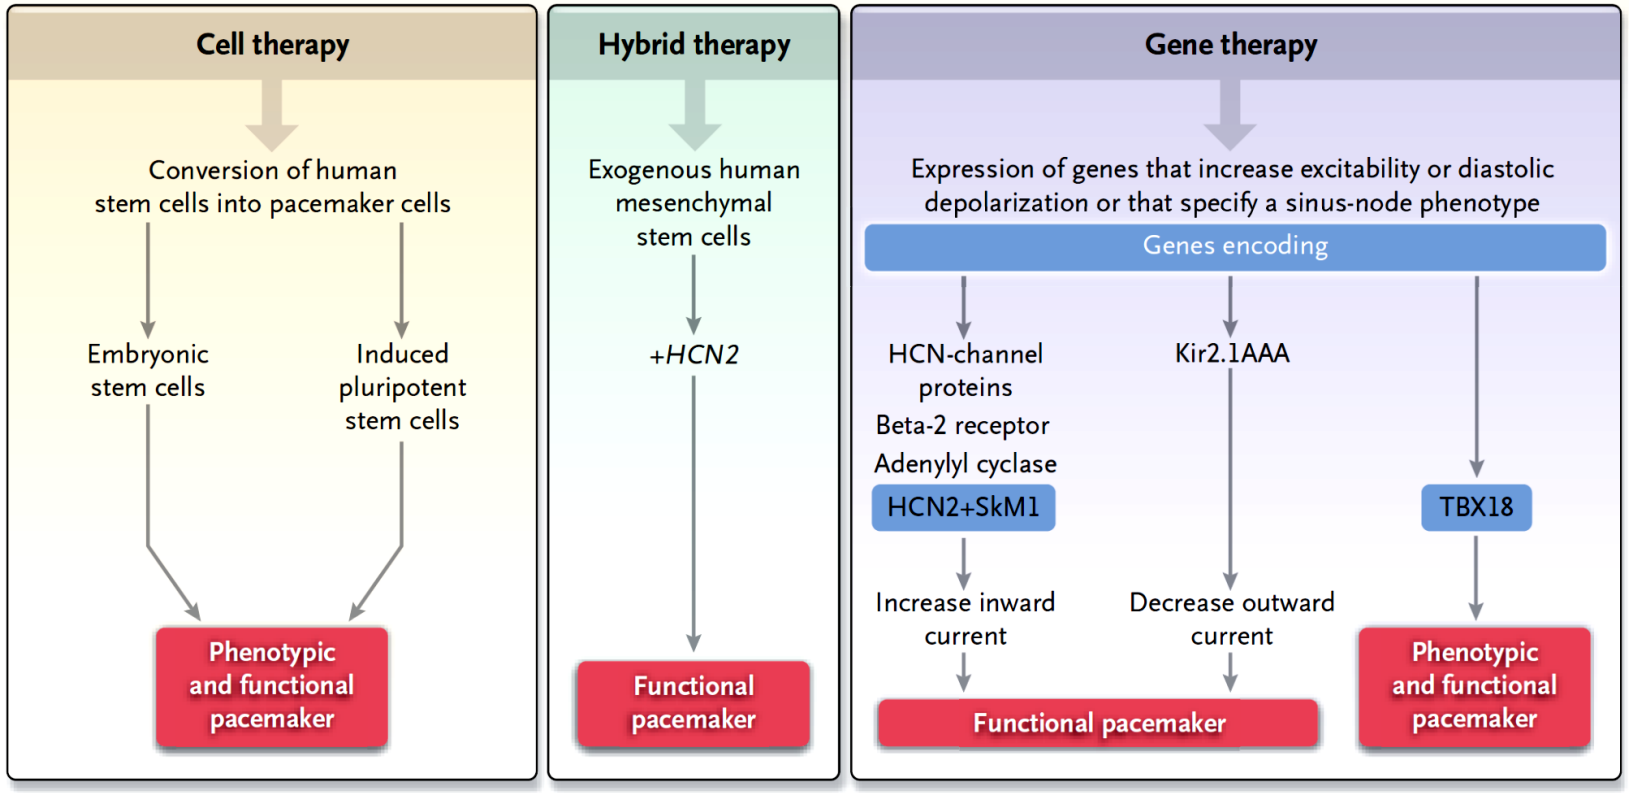

Figure 1. Approaches to Biological Pacing.

Cell therapy, gene therapy, and a hybrid approach have been used to create biological pacemakers in which the outcome is a cell that has the properties and function of a phenotypic pacemaker or that retains its adult phenotype but still takes on pacemaker function. Human embryonic stem cells or induced pluripotent stem cells engineered from mature fibroblasts or keratinocytes have been used to create a cardiac phenotypic and functional pacemakers in large animals. In hybrid therapy, a human mesenchymal stem cell loaded with the pacemaker gene *HCN2* (hyperpolarization-activated, cyclic nucleotide-gated channel 2) is implanted in the myocardium to induce pacemaker function. The gene encoding transcription factor TBX18 has also been used to engineer phenotypic and functional pacemaker cells from myocardial cells in situ. Gene therapies have used viral vectors or other means to overexpress the ion channels of the HCN pacemaker family, the skeletal-muscle sodium channel (SkM1), or the beta-2 receptor or adenylyl cyclase to increase inward current during diastole and have used the potassium-channel Kir2.1AAA to decrease outward current during diastole. Cell therapy, gene therapy, and hybrid therapy all increase pacemaker rate. Pacemaker function most closely approximating that envisioned as ideal occurs through the two gene therapies highlighted in blue.

Key points

- Biological pacing is a disruptive technology that aims first to improve upon, then to supplement and, eventually, to replace electronic pacing
- Biological pacing utilizes the tools of gene and cell therapy to introduce pacemaker function to preselected regions of the heart
- Gene therapy focuses on delivery via viral vectors; whereas cell therapy uses either mesenchymal stem cells as delivery systems or cells with sinoatrial node-like properties derived from pluripotent stem cells
- Proof-of-concept has been achieved in studies of large animals in complete heart block and, in some instances, sinoatrial node dysfunction
- Substantial barriers remain to be overcome before clinical trials of biological pacing can be begun, but the field is advancing steadily towards this goal

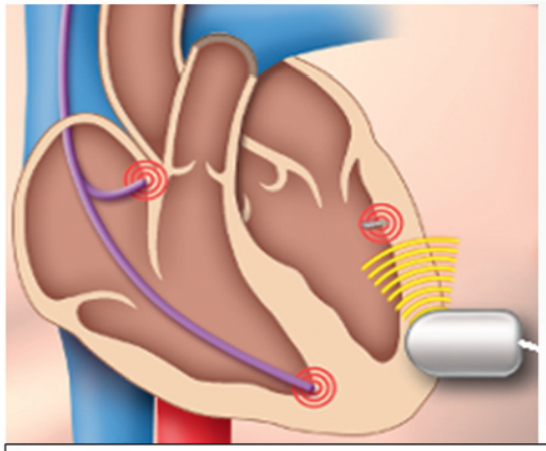
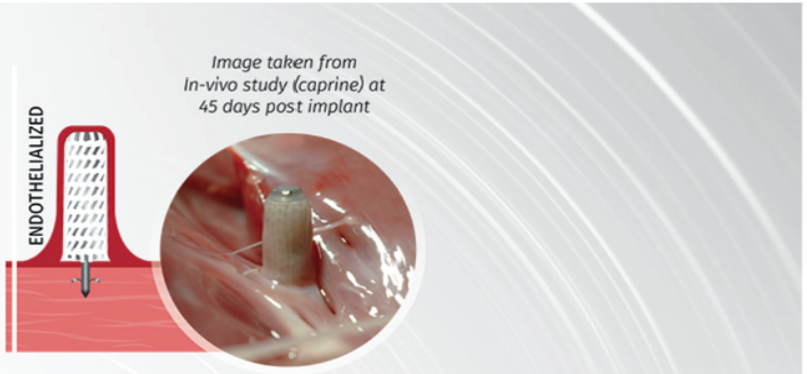
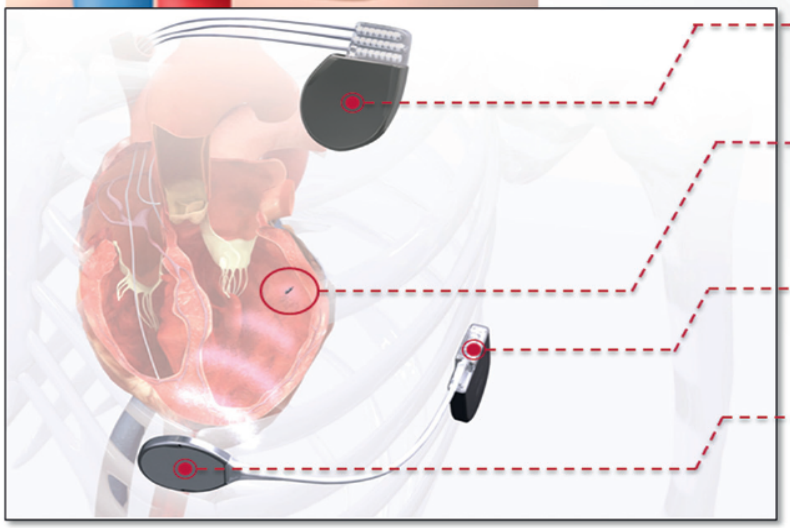
Ultrasound

FIGURE 17 Multicomponent Leadless Pacing System







CO-IMPLANT DEVICE
Co-implanted pacemaker, ICD or CRT paces the right ventricle.

RECEIVER ELECTRODE
Implanted onto the endocardium, the receiver electrode converts ultrasound energy into electrical energy to pace the left ventricle.

BATTERY
Implanted subcutaneously on the left mid axillary line, powers the transmitter.

TRANSMITTER
Phased array ultrasound transmitter is implanted sub-muscular over a cardiac echo window. Synchronizes with an RV pacing pulse to transmit ultrasound energy to the receiver electrode to provide Bi-V endocardial pacing.

The battery/transmitter unit detects the pacing stimulus from the coimplant, and an ultrasound pulse is sent to the receiver electrode, which converts the ultrasound energy to a pacing pulse. ICD = implantable cardioverter-defibrillator; other abbreviations as in Figures 1 and 3.

Micra™ (Medtronic)

Device Features

Size

- Volume: 0.75cc
- Mass: 2g
- Length: 25.9mm
- Width: 20Fr

Capabilities

- Pacing Mode: VVIR
- Bipolar sensing (18mm spacing)
- Programmable (RF communication with programmer)
- Capture Management
- Rate Response
- *Essential Diagnostics*: battery status, pacing threshold, pacing impedance, % paced
- Device can be manually deactivated and automatically deactives at EOS

Battery

- 9.6 / 7.1 year longevity
  - 1.5V / 2.0V threshold if 100% paced @ 60 bpm

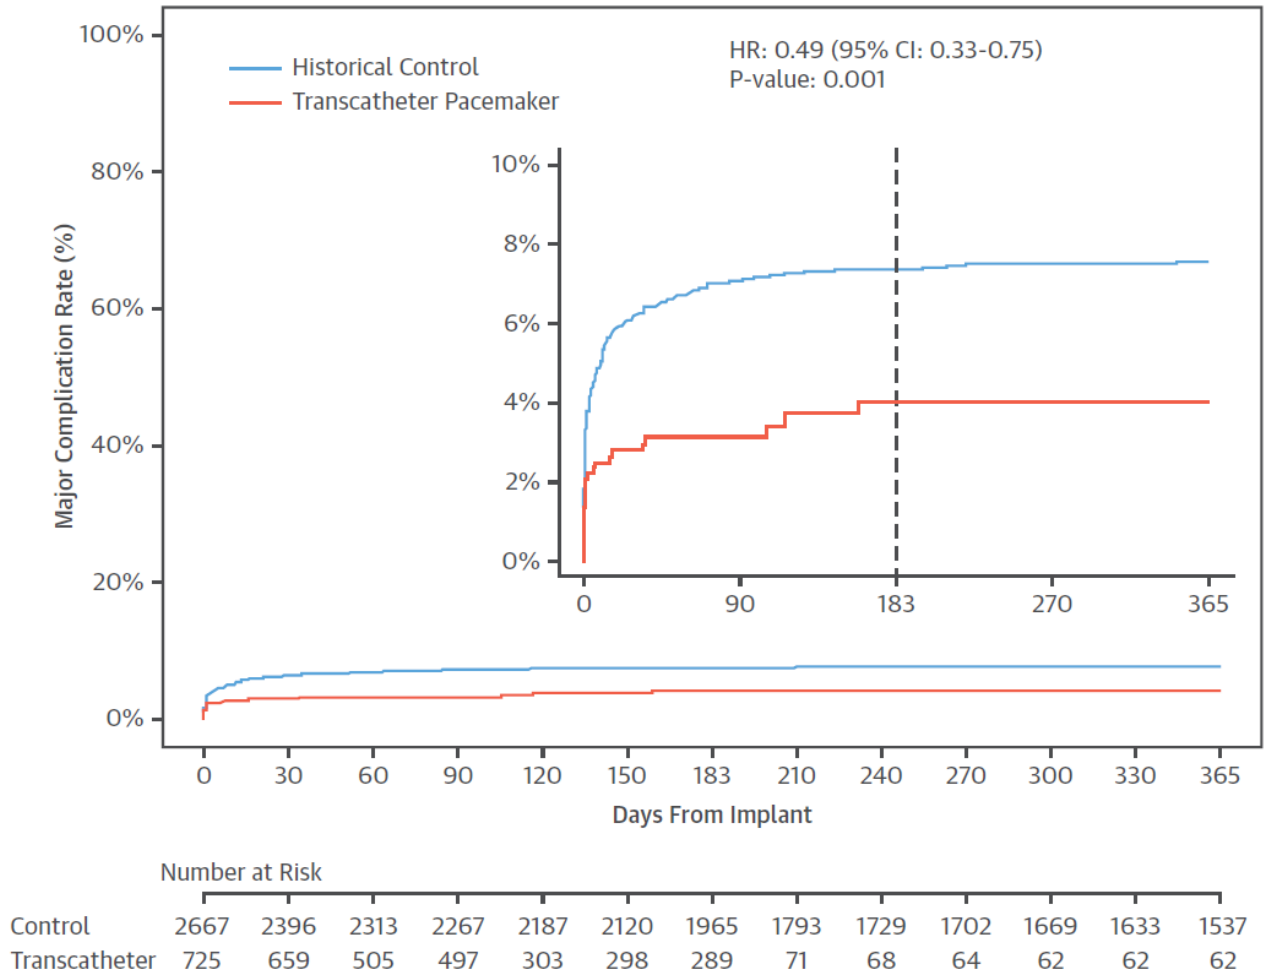
FIGURE 16 Complications With Transcatheter Leadless Pacemakers Versus Historical Transvenous Control Subjects



In this Micra TPS (Medtronic, Minneapolis, Minnesota) study post hoc analysis, the 725 study patients were compared with 2,667 patients who received transvenous pacemakers in previous studies as a historical control cohort. Leadless study patients were older and had more comorbidities than control subjects. At 6-month follow-up, patients with leadless pacemakers had significantly fewer major complications than control patients (HR: 0.49; $p < 0.001$), with study patients experiencing fewer hospitalizations, system revisions, and dislodgments. Reprinted with permission from Reynolds et al. (63). Abbreviations as in Figure 4.

Right Ventricular Anatomy Can Accommodate Multiple Micra Transcatheter Pacemakers

PAMELA OMDAHL, M.B.A.,* MICHAEL D. EGGEN, PH.D.,* MATTHEW D. BONNER, PH.D.,* PAUL A. IAIZZO, PH.D.,† and KENT WIKA, M.S.*

From the *Medtronic, PLC., Mounds View, Minnesota; and †Department of Surgery, University of Minnesota, Minneapolis, Minnesota

Methods: *A total of six human cadaver hearts were obtained from the University of Minnesota Anatomy Bequest Program; the seventh heart was a heart not deemed viable for transplant obtained from LifeSource and then reanimated using Visible Heart® methodologies. Each heart was implanted with multiple Micras using imaging and proper delivery tools; in these, the right ventricular volumes were measured and recorded. The hearts were subsequently dissected to view the right ventricular anatomies and the positions and spacing between devices.*

Results: *Multiple Micra devices could be placed in each heart in traditional, clinically accepted pacing implant locations within the RV and in each case without physical device interactions. This was true even in a human heart considered to be relatively small.*

Conclusions: *Although this technology is new, it was demonstrated here that within the human heart's RV, three Micra devices could be accommodated within traditional pacing locations: with the potential in some, for even more. (PACE 2016; 39:393–397)*

Long-term Outcomes in Leadless Micra Transcatheter Pacemakers with Elevated Thresholds at Implantation: Results from the Micra TPS Global Clinical Trial

Results: Among 711 Micra patients, 83 (11.7%) had an implant threshold >1.0 V at 0.24 msec. Among 538 Capture patients, 50 (9.3%) had an implant threshold of >1.0 V at 0.40 msec. There were no significant differences in patient characteristics between those with and without an implant threshold >1.0 V, with the exception of LVEF in the Capture cohort (lower with high thresholds, 53% vs 58%, p=0.011). Patients with implant thresholds >1.0 V decreased significantly (p<0.001) in both cohorts. Micra patients with high and very-high thresholds decreased significantly (p<0.01) by 1-month with 87% and 85% having 6-month thresholds lower than the implant value. However, when the capture threshold at implant was >2V only 18.2% had a threshold ≤1V at 6-months and 45.5% had a capture threshold >2V.

Methods and results

The study consists of two parts. *Animal experiments*: Two sheep were implanted with both an S-ICD and LP (Nanostim, SJM), and the objectives above were tested. *Human experience*: Follow-up of one S-ICD patient with bilateral subclavian occlusion who received an LP and two LP (all Nanostim, SJM) patients (without S-ICD) who received electrical cardioversion (ECV) are presented. *Animal experiments* : Simultaneous device-programmer communication was successful, but LP-programmer communication telemetry was temporarily lost (2 ± 2 s) during ventricular fibrillation (VF) induction and 4/54 shocks. Leadless pacemaker communication and pacing did not interfere with S-ICD rhythm discrimination. Additionally, all VF episodes ($n = 12/12$), including during simultaneous LP pacing, were detected and treated by the S-ICD. Post-shock LP performance was unaltered, and no post-shock device resets or dislodgements were observed (24 S-ICD and 30 external shocks). *Human experience* : The S-ICD/LP patient showed adequate S-ICD sensing during intrinsic rhythm, nominal, and high-output LP pacing. Two LP patients (without S-ICD) received ECV during follow-up. No impact on performance or LP dislodgements were observed.

Conclusion

Combined LP and S-ICD therapy appears feasible in all animal experiments ($n = 2$) and in one human subject. No interference in sensing and pacing during intrinsic and paced rhythm was noted in both animal and human subjects. However, induced arrhythmia testing was not performed in the patient. Defibrillation therapy did not seem to affect LP function. More data on safety and performance are needed.
